Cryptococcal Antigen Testing in an Integrated Medical System: Eastern Wisconsin

Marianne Klumph, MA; Brian Hoeynck, BS; Dennis J. Baumgardner, MD

INTRODUCTION

Cryptococcosis (crypto) is a serious environmentally-acquired endemic fungal infection causing meningitis, pneumonia and disseminated disease in usually immunocompromised hosts.

Proper diagnosis is important to avoid increased morbidity and mortality.

BACKGROUND

We aimed to explore the geodemographic and clinical features of Eastern Wisconsin patients tested with CrAg.

OBJECTIVE

We aimed to explore the geodemographic and clinical features of Eastern Wisconsin patients tested with CrAg.

METHODS

Design

• Retrospective review of 1465 CrAg tests from January, 2013 through April, 2017 for geodemographic characteristics and clinical features.

• If patient was ever positive, they were always considered positive; and the demographics, clinical feature were also used from the first identified positive test.

• If patient was always negative, we took information from the first test done during the time period.

• Descriptive statistics were compared with chi-square or t-tests; binary logistic regression was used for multivariable analysis.

Participants

• Every patient having CrAg performed within time period.

Setting

• Large Eastern Wisconsin medical system.

RESULTS

• A total of 1465 CrAg (741 on serum, 723 on CSF, 1 other) were performed on 1211 unique patients (50.2% female, 73.9% White, mean age 53.7 +/-16.5) during this time.

• Overall:
  • CrAg was positive in 23/1211 patients (1.9%)
  • 4 cases had pneumonia only
  • 21/23 were immunocompromised (6 transplant patients, 5 HIV, 4 malignancy, 3 steroid use, 2 diabetes, 1 combined deficiency)
  • Positive patients were more likely to be male (82.6%) non-Hispanic White (12/23 [3.8% of those tested] vs 11/23 [1.2% of those tested])
  • These associations (both p<0.03), but not age, were significant independent predictors in multivariable models.

• Positive patients were more likely in Milwaukee Zip codes (9.1% of those tested vs. 1.1% rest of the state, likely due to increase in immunocompromised patients); no other case clustering or close proximity to waterways was observed (41% were <162m from green space, similar to historical controls).

ACKNOWLEDGEMENT

• Special thanks to Kayla Heslin, MPH, for the creation of WI map to represent zip codes with positive crypto cases, and to Jessica Kram, MPH, for providing valuable feedback throughout the project.
